

CEN4025C Module 5 Project

The repo for this project contains the frontend code from Ch. 15 of the text and the backend code from Ch. 8. Create a clone and execute the project. You will need to perform the following steps:

- Create the springDevDb postgres database (no schema or data is required, the backend will create the tables and columns).
- Build and execute the backend first so the frontend can connect.
- Build and execute the frontend.
- Create the user and password as described in the textbook.
- Execute the Cypress E2E tests as described in the textbook.

Be sure to start both the backend and frontend before running the tests.

Submit 4 screen snips to your repo:

- Snip the Cypress dashboard after running the tests.
- Find the file in the source code which loads the user data from the fixture file after visiting the home page; screen snip that part of the code file.
- Find the file in the source code which creates the default configuration for E2E testing in cypress; screen snip that file.
- Find the file in the source code which creates a custom command to intercept an HTTP GET request and mock its response; screen snip that part of the code file.

Submit your working project to the GH Classroom repo, include your screen snips from the above steps.

NOTES:

To create the postgres DB:

Add postgres to your path **PATH=%PATH%C:\Program Files\PostgreSQL\16\bin**

Log in to postgres **psql -U postgres**

Enter the password (on Horizon: **P@ssw0rd1**)

Create the DB **create database "springDevDb";**

Use \c to verify \c **"springDevDb"**

After building and starting the backend, you can use \dt to view the database tables and \t to view the contents of the tables. You can monitor the backend logs if desired as you execute the frontend commands.

Building the frontend:

- You will need to run **npm install --force** to bypass some of the dependencies before building.
- Use **npx ng ...** if ng is not in the execution path
